8-BIT MICROPROCESSING UNIT

The MC6809 is a revolutionary high-performance 8-bit microprocessor which supports modern programming techniques such as position independence, reentrancy, and modular programming.

This third-generation addition to the M6800 Family has major architectural improvements which include additional registers, instructions, and addressing modes.

The basic instructions of any computer are greatly enhanced by the presence of powerful addressing modes. The MC6809 has the most complete set of addressing modes available on any 8-bit microprocessor today.

The MC6809 has hardware and software features which make it an ideal processor for higher level language execution or standard controller applications.

MC6800 COMPATIBLE

- Hardware — Interfaces with All M6800 Peripherals
- Software — Upward Source Code Compatible Instruction Set and Addressing Modes

ARCHITECTURAL FEATURES

- Two 16-Bit Index Registers
- Two 16-Bit Indexable Stack Pointers
- Two 8-Bit Accumulators can be Concatenated to Form One 16-Bit Accumulator
- Direct Page Register Allows Direct Addressing Throughout Memory

HARDWARE FEATURES

- On-Chip Oscillator (Crystal Frequency = $4 \times E$)
- DMA/BREQ Allows DMA Operation on Memory Refresh
- Fast Interrupt Request Input Stacks Only Condition Code Register and Program Counter
- MRDY Input Extends Data Access Times for Use with Slow Memory
- Interrupt Acknowledge Output Allows Vectoring by Devices
- Sync Acknowledge Output Allows for Synchronization to External Event
- Single Bus-Cycle RESET
- Single 5-Volt Supply Operation
- NMI Inhibited After RESET Until After First Load of Stack Pointer
- Early Address Valid Allows Use with Slower Memories
- Early Write Data for Dynamic Memories

SOFTWARE FEATURES

- 10 Addressing Modes
 - 6800 Upward Compatible Addressing Modes
 - Direct Addressing Anywhere in Memory Map
 - Long Relative Branches
 - Program Counter Relative
 - True Indirect Addressing
 - Expanded Indexed Addressing:
 - 0-, 5-, 8-, or 16-Bit Constant Offsets
 - 8- or 16-Bit Accumulator Offsets
 - Auto Increment/Decrement by 1 or 2
- Improved Stack Manipulation
- 1464 Instructions with Unique Addressing Modes
- 8×8 Unsigned Multiply
- 16-Bit Arithmetic
- Transfer/Exchange All Registers
- Push/Pull Any Registers or Any Set of Registers
- Load Effective Address

MAXIMUM RATINGS

Rating	Symbol	Value	Unit
Supply Voltage	V_{CC}	-0.3 to +7.0	V
Input Voltage	V_{in}	-0.3 to +7.0	V
Operating Temperature Range MC6809, MC68A09, MC68B09 MC6809C, MC68A09C, MC68B09C	T_A	T_L to T_H 0 to +70 -40 to +85	°C
Storage Temperature Range	T_{stg}	-55 to +150	°C

THERMAL CHARACTERISTICS

Characteristic	Symbol	Value	Unit
Thermal Resistance Ceramic Cerdip Plastic	θ_{JA}	50 60 100	°C/W

This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum rated voltages to this high impedance circuit. Reliability of operation is enhanced if unused inputs are tied to an appropriate logic voltage levels (e.g., either V_{SS} or V_{CC}).

POWER CONSIDERATIONS

The average chip-junction temperature, T_J , in °C can be obtained from:

$$T_J = T_A + (P_D \cdot \theta_{JA}) \quad (1)$$

Where:

T_A ≡ Ambient Temperature, °C

θ_{JA} ≡ Package Thermal Resistance, Junction-to-Ambient, °C/W

P_D ≡ $P_{INT} + P_{PORT}$

P_{INT} ≡ $I_{CC} \times V_{CC}$, Watts — Chip Internal Power

P_{PORT} ≡ Port Power Dissipation, Watts — User Determined

For most applications $P_{PORT} \ll P_{INT}$ and can be neglected. P_{PORT} may become significant if the device is configured to drive Darlington bases or sink LED loads.

An approximate relationship between P_D and T_J (if P_{PORT} is neglected) is:

$$P_D = K + (T_J + 273^\circ\text{C}) \quad (2)$$

Solving equations 1 and 2 for K gives:

$$K = P_D \cdot (T_A + 273^\circ\text{C}) + \theta_{JA} \cdot P_D^2 \quad (3)$$

Where K is a constant pertaining to the particular part. K can be determined from equation 3 by measuring P_D (at equilibrium) for a known T_A . Using this value of K the values of P_D and T_J can be obtained by solving equations (1) and (2) iteratively for any value of T_A .

ELECTRICAL CHARACTERISTICS ($V_{CC}=5.0\text{ V} \pm 5\%$, $V_{SS}=0$, $T_A=T_L$ to T_H unless otherwise noted)

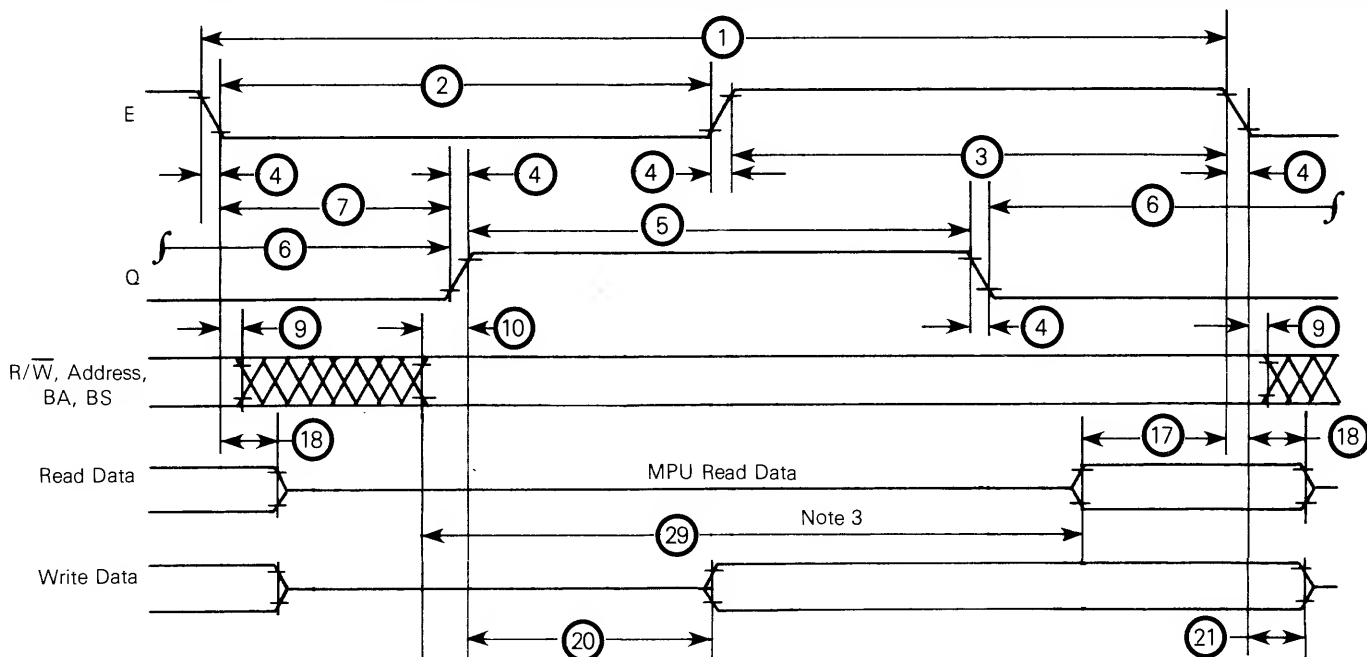

Characteristic	Symbol	Min	Typ	Max	Unit

* Address and data hold times are periodically tested rather than 100% tested.

NOTES:

1. Voltage levels shown are $V_L \leq 0.4 V$, $V_H \geq 2.4 V$, unless otherwise specified.
2. Measurement points shown are 0.8 V and 2.0 V, unless otherwise specified.
3. Usable access time is computed by: $1 - 4 - 7 \text{ max} + 10 - 17$.
4. Hold time (9) for BA and BS is not specified.
5. Maximum t_{cyc} during MRDY or DMA/BREQ is 16 μs .

 $R = 11.7 \text{ k}\Omega$ for D0-D7
 $16.5 \text{ k}\Omega$ for A0-A15, E, Q, R/W
 $24 \text{ k}\Omega$ for BA, BS

PROGRAMMING MODEL

As shown in Figure 4, the MC6809 adds three registers to the set available in the MC6800. The added registers include a direct page register, the user stack pointer, and a second index register.

ACCUMULATORS (A, B, D)

The A and B registers are general purpose accumulators which are used for arithmetic calculations and manipulation of data.

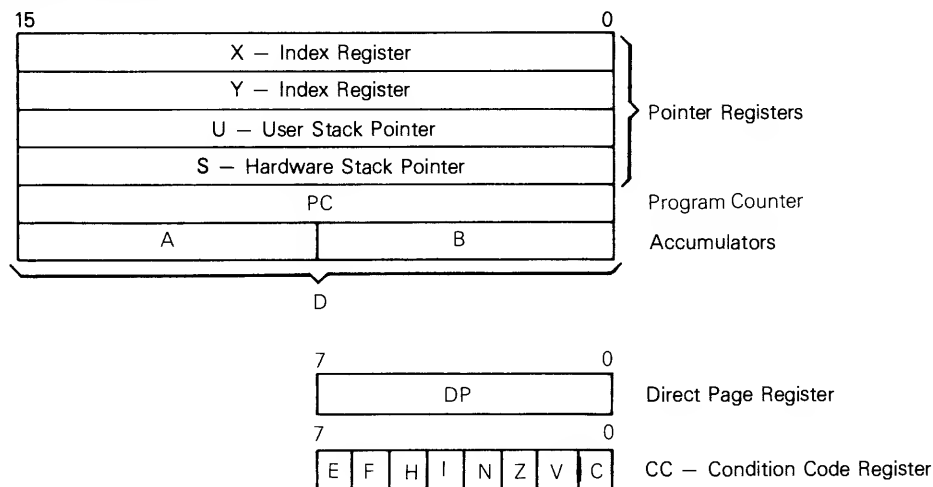

Certain instructions concatenate the A and B registers to form a single 16-bit accumulator. This is referred to as the D register, and is formed with the A register as the most significant byte.

DIRECT PAGE REGISTER (DP)

The direct page register of the MC6809 serves to enhance the direct addressing mode. The content of this register appears at the higher address outputs (A8-A15) during direct addressing instruction execution. This allows the direct mode to be used at any place in memory, under program control. To ensure M6800 compatibility, all bits of this register are cleared during processor reset.

FIGURE 4 — PROGRAMMING MODEL OF THE MICROPROCESSING UNIT

INDEX REGISTERS (X, Y)

The index registers are used in indexed mode of addressing. The 16-bit address in this register takes part in the calculation of effective addresses. This address may be used to point to data directly or may be modified by an optional constant or register offset. During some indexed modes, the contents of the index register are incremented or decremented to point to the next item of tabular type data. All four pointer registers (X, Y, U, S) may be used as index registers.

STACK POINTER (U, S)

The hardware stack pointer (S) is used automatically by the processor during subroutine calls and interrupts. The stack pointers of the MC6809 point to the top of the stack, in contrast to the MC6800 stack pointer, which pointed to the next free location on the stack. The user stack pointer (U) is controlled exclusively by the programmer. This allows arguments to be passed to and from subroutines with ease. Both stack pointers have the same indexed mode addressing capabilities as the X and Y registers, but also support **Push** and **Pull** instructions. This allows the MC6809 to be used efficiently as a stack processor, greatly enhancing its ability to support higher level languages and modular programming.

PROGRAM COUNTER

The program counter is used by the processor to point to the address of the next instruction to be executed by the processor. Relative addressing is provided allowing the program counter to be used like an index register in some situations.

CONDITION CODE REGISTER

The condition code register defines the state of the processor at any given time. See Figure 5.

FIGURE 5 — CONDITION CODE REGISTER FORMAT

CONDITION CODE REGISTER DESCRIPTION

BIT 0 (C)

Bit 0 is the carry flag, and is usually the carry from the binary ALU. C is also used to represent a 'borrow' from subtract-like instructions (CMP, NEG, SUB, SBC) and is the complement of the carry from the binary ALU.

BIT 1 (V)

Bit 1 is the overflow flag, and is set to a one by an operation which causes a signed two's complement arithmetic overflow. This overflow is detected in an operation in which the carry from the MSB in the ALU does not match the carry from the MSB-1.

BIT 2 (Z)

Bit 2 is the zero flag, and is set to a one if the result of the previous operation was identically zero.

BIT 3 (N)

Bit 3 is the negative flag, which contains exactly the value of the MSB of the result of the preceding operation. Thus, a negative twos-complement result will leave N set to a one.

BIT 4 (I)

Bit 4 is the $\overline{\text{IRQ}}$ mask bit. The processor will not recognize interrupts from the $\overline{\text{IRQ}}$ line if this bit is set to a one. $\overline{\text{NMI}}$, $\overline{\text{FIRQ}}$, $\overline{\text{IRQ}}$, $\overline{\text{RESET}}$, and SWI all set I to a one. SWI2 and SWI3 do not affect I.

BIT 5 (H)

Bit 5 is the half-carry bit, and is used to indicate a carry from bit 3 in the ALU as a result of an 8-bit addition only (ADC or ADD). This bit is used by the DAA instruction to perform a BCD decimal add adjust operation. The state of this flag is undefined in all subtract-like instructions.

BIT 6 (F)

Bit 6 is the $\overline{\text{FIRQ}}$ mask bit. The processor will not recognize interrupts from the $\overline{\text{FIRQ}}$ line if this bit is a one. $\overline{\text{NMI}}$, $\overline{\text{FIRQ}}$, SWI, and $\overline{\text{RESET}}$ all set F to a one. $\overline{\text{IRQ}}$, SWI2, and SWI3 do not affect F.

BIT 7 (E)

Bit 7 is the entire flag, and when set to a one indicates that the complete machine state (all the registers) was stacked, as opposed to the subset state (PC and CC). The E bit of the stacked CC is used on a return from interrupt (RTI) to determine the extent of the unstacking. Therefore, the current E left in the condition code register represents past action.

PIN DESCRIPTIONS

POWER (VSS, VCC)

Two pins are used to supply power to the part: VSS is ground or 0 volts, while VCC is +5.0 V $\pm 5\%$.

ADDRESS BUS (A0-A15)

Sixteen pins are used to output address information from the MPU onto the address bus. When the processor does not require the bus for a data transfer, it will output address FFFF₁₆, $\text{R}/\overline{\text{W}} = 1$, and $\text{BS} = 0$; this is a "dummy access" or VMA cycle. Addresses are valid on the rising edge of Q. All address bus drivers are made high impedance when output bus available (BA) is high. Each pin will drive one Schottky TTL load or four LSTTL loads, and 90 pF.

DATA BUS (D0-D7)

These eight pins provide communication with the system bidirectional data bus. Each pin will drive one Schottky TTL load or four LSTTL loads, and 130 pF.

READ/WRITE (R/ $\overline{\text{W}}$)

This signal indicates the direction of data transfer on the data bus. A low indicates that the MPU is writing data onto the data bus. $\text{R}/\overline{\text{W}}$ is made high impedance when BA is high. $\text{R}/\overline{\text{W}}$ is valid on the rising edge of Q.

 $\overline{\text{RESET}}$

A low level on this Schmitt-trigger input for greater than one bus cycle will reset the MPU, as shown in Figure 6. The reset vectors are fetched from locations FFFE₁₆ and FFFF₁₆ (Table 1) when interrupt acknowledge is true, ($\text{BA} \bullet \text{BS} = 1$). During initial power on, the $\overline{\text{RESET}}$ line should be held low until the clock oscillator is fully operational. See Figure 7.

Because the MC6809 $\overline{\text{RESET}}$ pin has a Schmitt-trigger input with a threshold voltage higher than that of standard peripherals, a simple R/C network may be used to reset the entire system. This higher threshold voltage ensures that all peripherals are out of the reset state before the processor.

 $\overline{\text{HALT}}$

A low level on this input pin will cause the MPU to stop running at the end of the present instruction and remain halted indefinitely without loss of data. When halted, the BA output is driven high indicating the buses are high impedance. BS is also high which indicates the processor is in the halt or bus grant state. While halted, the MPU will not respond to external real-time requests ($\overline{\text{FIRQ}}$, $\overline{\text{IRQ}}$) although DMA/BREQ will always be accepted, and $\overline{\text{NMI}}$ or $\overline{\text{RESET}}$ will be latched for later response. During the halt state, Q and E continue to run normally. If the MPU is not running ($\overline{\text{RESET}}$, DMA/BREQ), a halted state ($\text{BA} \bullet \text{BS} = 1$) can be achieved by pulling $\overline{\text{HALT}}$ low while $\overline{\text{RESET}}$ is still low. If DMA/BREQ and $\overline{\text{HALT}}$ are both pulled low, the processor will reach the last cycle of the instruction (by reverse cycle stealing) where the machine will then become halted. See Figure 8.

BUS AVAILABLE, BUS STATUS (BA, BS)

The bus available output is an indication of an internal control signal which makes the MOS buses of the MPU high impedance. This signal does not imply that the bus will be available for more than one cycle. When BA goes low, a dead cycle will elapse before the MPU acquires the bus.

The bus status output signal, when decoded with BA, represents the MPU state (valid with leading edge of Q).

MPU State		MPU State Definition
BA	BS	
0	0	Normal (Running)
0	1	Interrupt or Reset Acknowledge
1	0	Sync Acknowledge
1	1	Halt or Bus Grant Acknowledge

FIGURE 6 — RESET TIMING

- NOTES: 1. Parts with date codes prefixed by 7F or 5A will come out of $\overline{\text{RESET}}$ one cycle sooner than shown.
2. Timing measurements are referenced to and from a low voltage of 0.8 volts and a high voltage of 2.0 volts, unless otherwise noted.
3. FFFE appears on the bus during $\overline{\text{RESET}}$ low time. Following the active transition of the $\overline{\text{RESET}}$ line, three more FFFE cycles will appear followed by the vector fetch.

FIGURE 7 — CRYSTAL CONNECTIONS AND OSCILLATOR START UP

NOTE: Waveform measurements for all inputs and outputs are specified at logic high 2.0 V and logic low 0.8 V unless otherwise specified.

Y1	C_{in}	C_{out}
8 MHz	18 pF	18 pF
6 MHz	20 pF	20 pF
4 MHz	24 pF	24 pF

Nominal Crystal Parameters

	3.58 MHz	4.00 MHz	6.0 MHz	8.0 MHz
R_S	60 Ω	50 Ω	30-50 Ω	20-40 Ω
$C0$	3.5 pF	6.5 pF	4-6 pF	4-6 pF
$C1$	0.015 pF	0.025 pF	0.01-0.02 pF	0.01-0.02 pF
Q	>40 k	>30 k	>20 k	>20 k

All parameters are 10%

NOTE: These are representative AT-cut crystal parameters only. Crystals of other types of cut may also be used.

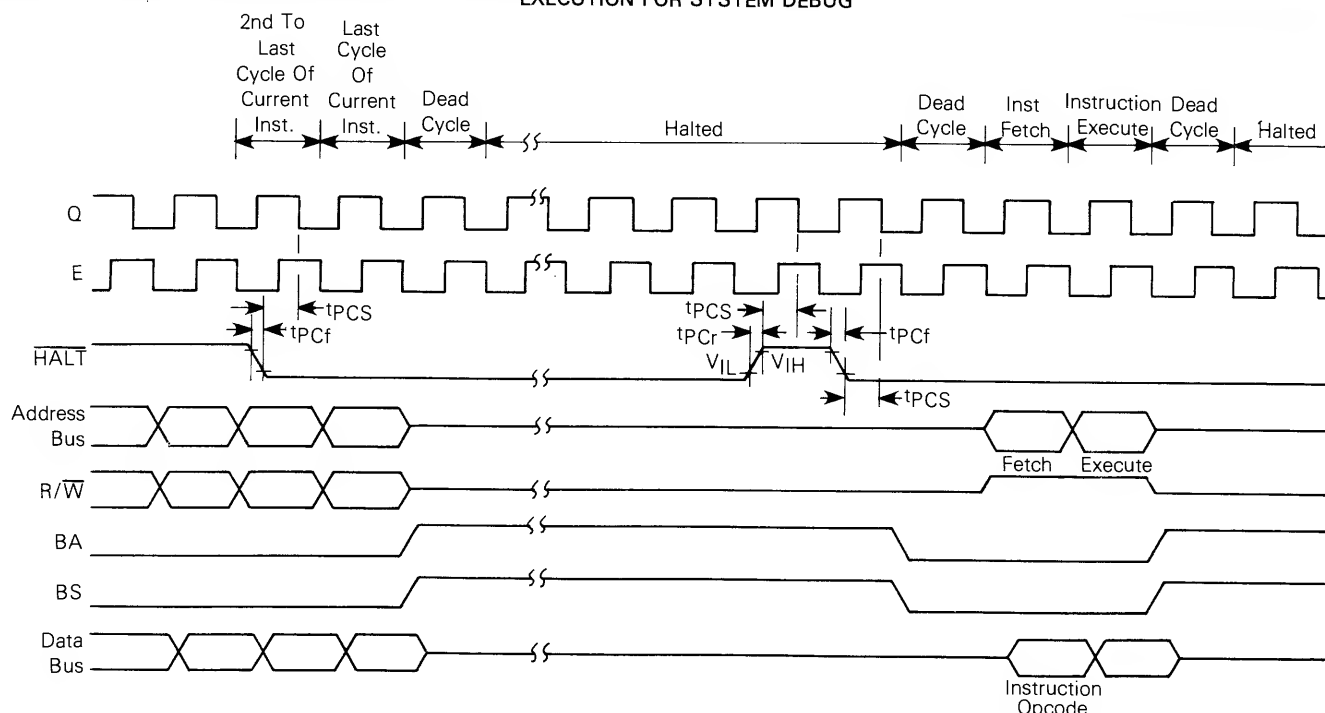

FIGURE 8 — $\overline{\text{HALT}}$ AND SINGLE INSTRUCTION EXECUTION FOR SYSTEM DEBUG

NOTE: Waveform measurements for all inputs and outputs are specified at logic high 2.0 V and logic low 0.8 V unless otherwise specified.

INTERRUPT ACKNOWLEDGE is indicated during both cycles of a hardware-vector-fetch ($\overline{\text{RESET}}$, $\overline{\text{NMI}}$, $\overline{\text{FIRQ}}$, $\overline{\text{IRQ}}$, SWI , SWI2 , SWI3). This signal, plus decoding of the lower four address lines, can provide the user with an indication of which interrupt level is being serviced and allow vectoring by device. See Table 1:

SYNC ACKNOWLEDGE is indicated while the MPU is waiting for external synchronization on an interrupt line.

HALT/BUS GRANT is true when the MC6809 is in a halt or bus grant condition.

TABLE 1 — MEMORY MAP FOR INTERRUPT VECTORS

Memory Map For Vector Locations		Interrupt Vector Description
MS	LS	
FFFE	FFFF	$\overline{\text{RESET}}$
FFFC	FFFD	$\overline{\text{NMI}}$
FFFA	FFFB	SWI
FFF8	FFF9	$\overline{\text{IRQ}}$
FFF6	FFF7	$\overline{\text{FIRQ}}$
FFF4	FFF5	SWI2
FFF2	FFF3	SWI3
FFF0	FFF1	Reserved

NON MASKABLE INTERRUPT ($\overline{\text{NMI}}$) *

A negative transition on this input requests that a non-maskable interrupt sequence be generated. A non-maskable

interrupt cannot be inhibited by the program, and also has a higher priority than $\overline{\text{FIRQ}}$, $\overline{\text{IRQ}}$, or software interrupts. During recognition of an $\overline{\text{NMI}}$, the entire machine state is saved on the hardware stack. After reset, an $\overline{\text{NMI}}$ will not be recognized until the first program load of the hardware stack pointer (S). The pulse width of $\overline{\text{NMI}}$ low must be at least one E cycle. If the $\overline{\text{NMI}}$ input does not meet the minimum set up with respect to Q, the interrupt will not be recognized until the next cycle. See Figure 9.

FAST-INTERRUPT REQUEST ($\overline{\text{FIRQ}}$) *

A low level on this input pin will initiate a fast interrupt sequence, provided its mask bit (F) in the CC is clear. This sequence has priority over the standard interrupt request ($\overline{\text{IRQ}}$), and is fast in the sense that it stacks only the contents of the condition code register and the program counter. The interrupt service routine should clear the source of the interrupt before doing an RTI. See Figure 10.

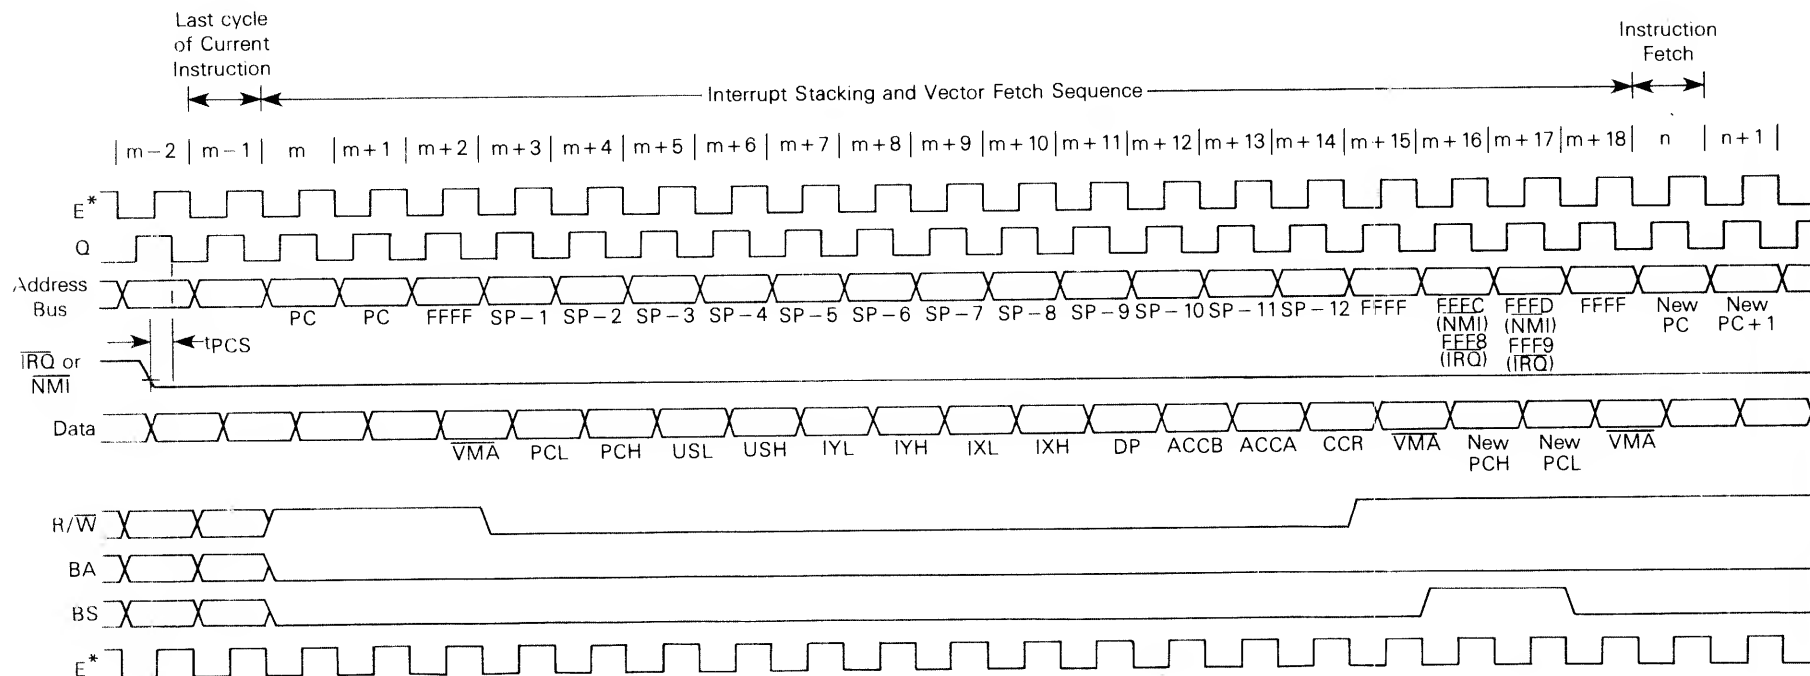

INTERRUPT REQUEST ($\overline{\text{IRQ}}$) *

A low level input on this pin will initiate an interrupt request sequence provided the mask bit (I) in the CC is clear. Since $\overline{\text{IRQ}}$ stacks the entire machine state it provides a slower response to interrupts than $\overline{\text{FIRQ}}$. $\overline{\text{IRQ}}$ also has a lower priority than $\overline{\text{FIRQ}}$. Again, the interrupt service routine should clear the source of the interrupt before doing an RTI. See Figure 9.

* $\overline{\text{NMI}}$, $\overline{\text{FIRQ}}$, and $\overline{\text{IRQ}}$ requests are sampled on the falling edge of Q. One cycle is required for synchronization before these interrupts are recognized. The pending interrupt(s) will not be serviced until completion of the current instruction unless a SYNC or CWAI condition is present. If $\overline{\text{IRQ}}$ and $\overline{\text{FIRQ}}$ do not remain low until completion of the current instruction they may not be recognized. However, $\overline{\text{NMI}}$ is latched and need only remain low for one cycle. No interrupts are recognized or latched between the falling edge of $\overline{\text{RESET}}$ and the rising edge of BS indicating $\overline{\text{RESET}}$ acknowledge.

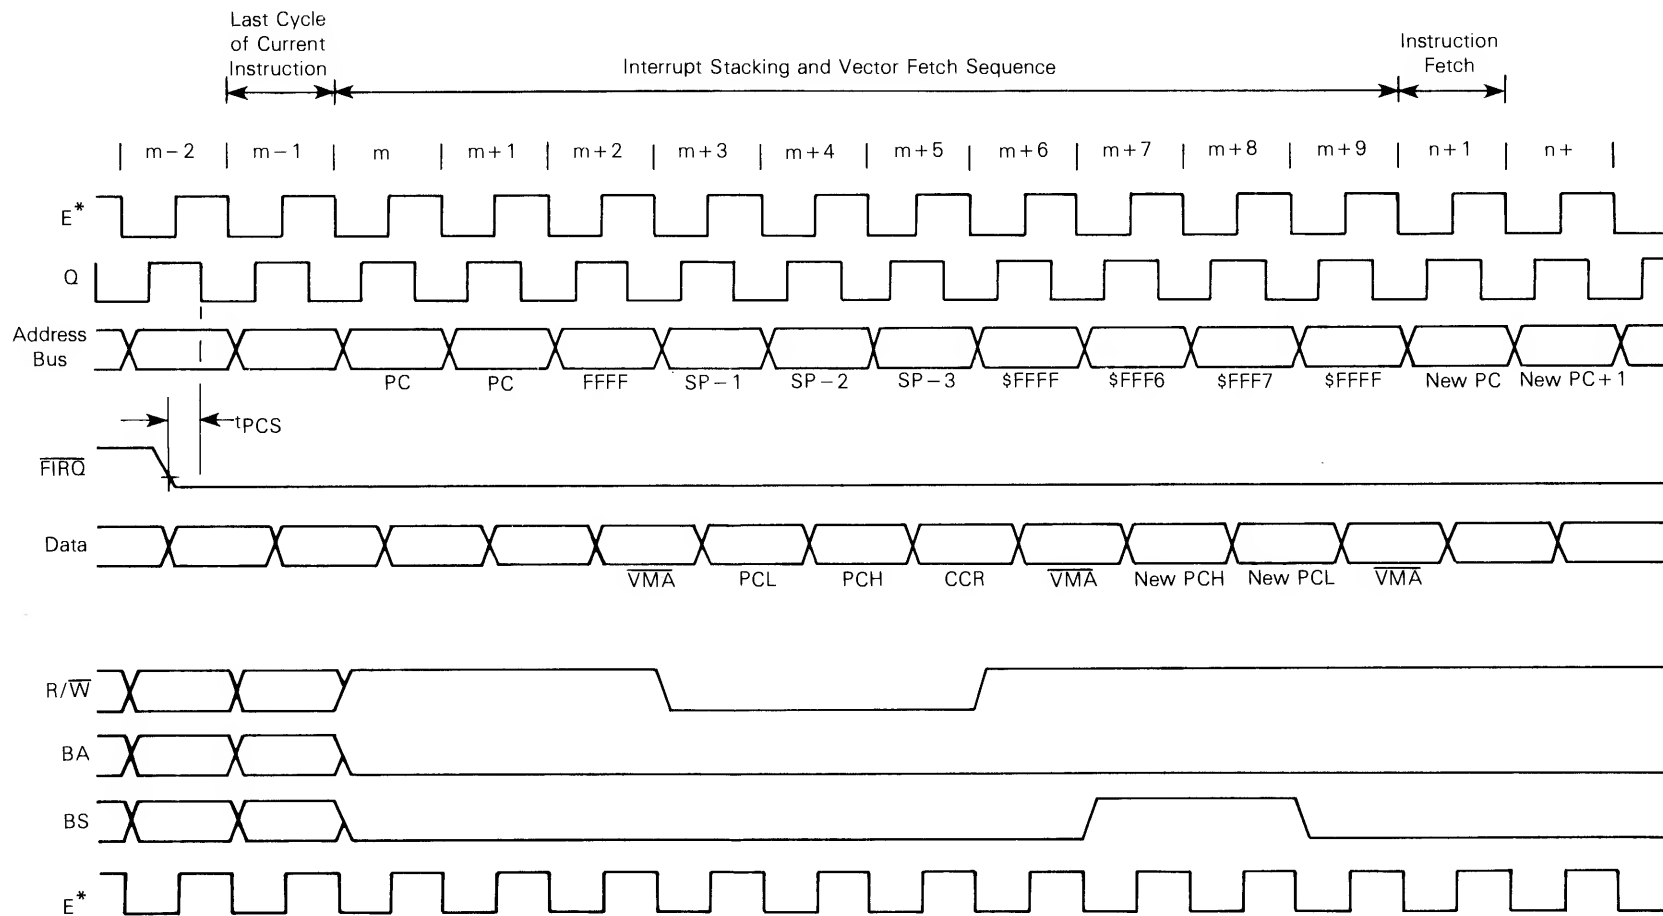

FIGURE 9 — $\overline{\text{IRQ}}$ AND $\overline{\text{NMI}}$ INTERRUPT TIMING

NOTE: Waveform measurements for all inputs and outputs are specified at logic high = 2.0 V and logic low = 0.8 V unless otherwise specified.

* E clock shown for reference only.

FIGURE 10 — $\overline{\text{FIRQ}}$ INTERRUPT TIMING

NOTE: Waveform measurements for all inputs and outputs are specified at logic high = 2.0 V and logic low = 0.8 V unless otherwise specified.

* E clock shown for reference only.

XTAL, EXTAL

These inputs are used to connect the on-chip oscillator to an external parallel-resonant crystal. Alternately, the pin EXTAL may be used as a TTL level input for external timing by grounding XTAL. The crystal or external frequency is four times the bus frequency. See Figure 7. Proper RF layout techniques should be observed in the layout of printed circuit boards.

E, Q

E is similar to the MC6800 bus timing signal phase 2; Q is a quadrature clock signal which leads E. Q has no parallel on the MC6800. Addresses from the MPU will be valid with the leading edge of Q. Data is latched on the falling edge of E. Timing for E and Q is shown in Figure 11.

MRDY*

This input control signal allows stretching of E and Q to extend data-access time. E and Q operate normally while MRDY is high. When MRDY is low, E and Q may be stretched in integral multiples of quarter ($\frac{1}{4}$) bus cycles, thus allowing interface to slow memories, as shown in Figure 12(a). During non-valid memory access ($\overline{\text{VMA}}$ cycles), MRDY has no effect on stretching E and Q; this inhibits slowing the processor during "don't care" bus accesses. MRDY may also be used to stretch clocks (for slow memory) when bus control has been transferred to an external device (through the use of $\overline{\text{HALT}}$ and $\overline{\text{DMA/BREQ}}$).

NOTE

Four of the early production mask sets (G7F, T5A, P6F, T6M) require synchronization of the MRDY input with the 4f clock. The synchronization necessitates an external oscillator as shown in Figure 12(b). The negative transition of the MRDY signal, normally derived from the chip select decoding, must meet the tPCS timing. With these four mask sets, MRDY's positive transition must occur with the rising edge of 4f.

In addition, on these same mask sets, MRDY will not stretch the E and Q signals if the machine is executing either a TFR or EXG instruction during the $\overline{\text{HALT}}$ high-to-low transition. If the MPU executes a CWA1 instruction, the machine pushes the internal

registers onto the stack and then awaits an interrupt. During this waiting period, it is possible to place the MPU into a halt mode to three-state the machine, but MRDY will not stretch the clocks.

The mask set for a particular part may be determined by examining the markings on top of the part. Below the part number is a string of characters. The first two characters are the last two characters of the mask set code. If there are only four digits the part is the G7F mask set. The last four digits, the date code, show when the part was manufactured. These four digits represent year and week. For example a ceramic part marked:

is a T5A mask set made the twelfth week of 1980.

DMA/BREQ*

The $\overline{\text{DMA/BREQ}}$ input provides a method of suspending execution and acquiring the MPU bus for another use, as shown in Figure 13. Typical uses include DMA and dynamic memory refresh.

A low level on this pin will stop instruction execution at the end of the current cycle unless pre-empted by self-refresh. The MPU will acknowledge $\overline{\text{DMA/BREQ}}$ by setting BA and BS to a one. The requesting device will now have up to 15 bus cycles before the MPU retrieves the bus for self-refresh. Self-refresh requires one bus cycle with a leading and trailing dead cycle. See Figure 14. The self-refresh counter is only cleared if $\overline{\text{DMA/BREQ}}$ is inactive for two or more MPU cycles.

Typically, the DMA controller will request to use the bus by asserting $\overline{\text{DMA/BREQ}}$ pin low on the leading edge of E. When the MPU replies by setting BA and BS to a one, that cycle will be a dead cycle used to transfer bus mastership to the DMA controller.

False memory accesses may be prevented during any dead cycles by developing a system $\overline{\text{DMAVMA}}$ signal which is LOW in any cycle when BA has changed.

FIGURE 11 — E/Q RELATIONSHIP

NOTE: Waveform measurements for all inputs and outputs are specified at logic high 2.0 V and logic low 0.8 V unless otherwise specified.

* The on-board clock generator furnishes E and Q to both the system and the MPU. When MRDY is pulled low, both the system clocks and the internal MPU clocks are stretched. Assertion of $\overline{\text{DMA/BREQ}}$ input stops the internal MPU clocks while allowing the external system clocks to RUN (i.e., release the bus to a DMA controller). The internal MPU clocks resume operation after $\overline{\text{DMA/BREQ}}$ is released or after 16 bus cycles (14 DMA, two dead), whichever occurs first. While $\overline{\text{DMA/BREQ}}$ is asserted it is sometimes necessary to pull MRDY low to allow DMA to/from slow memory/peripherals. As both MRDY and $\overline{\text{DMA/BREQ}}$ control the internal MPU clocks, care must be exercised not to violate the maximum t_{CYC} specification for MRDY or $\overline{\text{DMA/BREQ}}$. (Maximum t_{CYC} during MRDY or $\overline{\text{DMA/BREQ}}$ is 16 μs .)

When \overline{BA} goes low (either as a result of $\overline{DMA/BREQ} = \text{HIGH}$ or MPU self-refresh), the DMA device should be taken off the bus. Another dead cycle will elapse before the MPU accesses memory to allow transfer of bus mastership without contention.

MPU OPERATION

During normal operation, the MPU fetches an instruction from memory and then executes the requested function.

This sequence begins after \overline{RESET} and is repeated indefinitely unless altered by a special instruction or hardware occurrence. Software instructions that alter normal MPU operation are: \overline{SWI} , $\overline{SWI2}$, $\overline{SWI3}$, \overline{CWA} , \overline{RTI} , and \overline{SYNC} . An interrupt, \overline{HALT} , or $\overline{DMA/BREQ}$ can also alter the normal execution of instructions. Figure 15 illustrates the flowchart for the MC6809.

FIGURE 12 — MRDY TIMING AND SYNCHRONIZATION

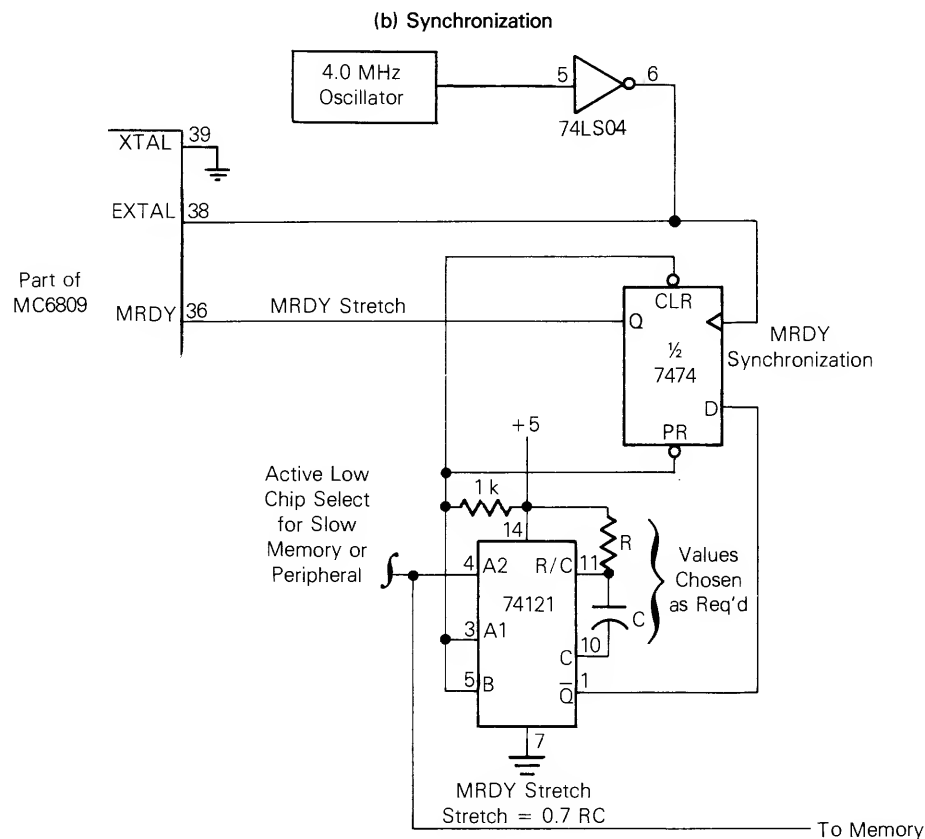

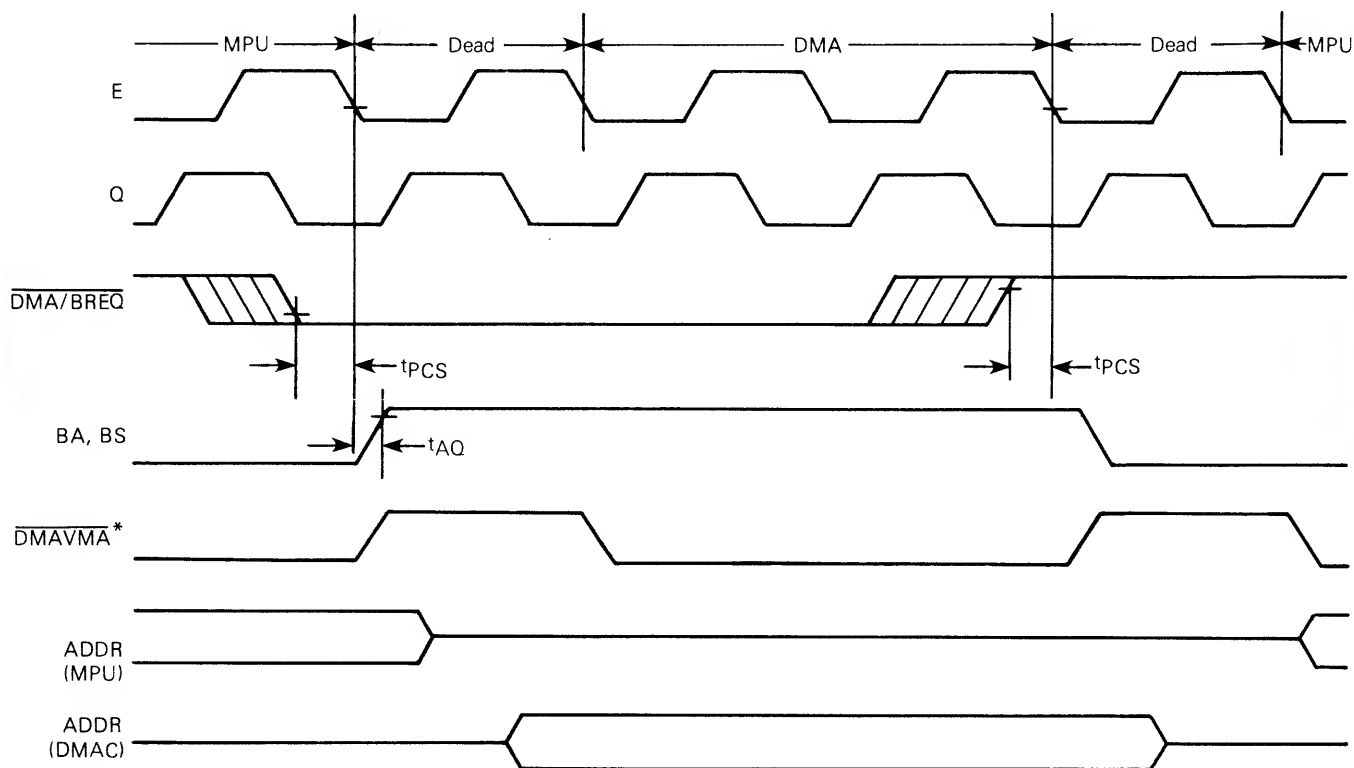

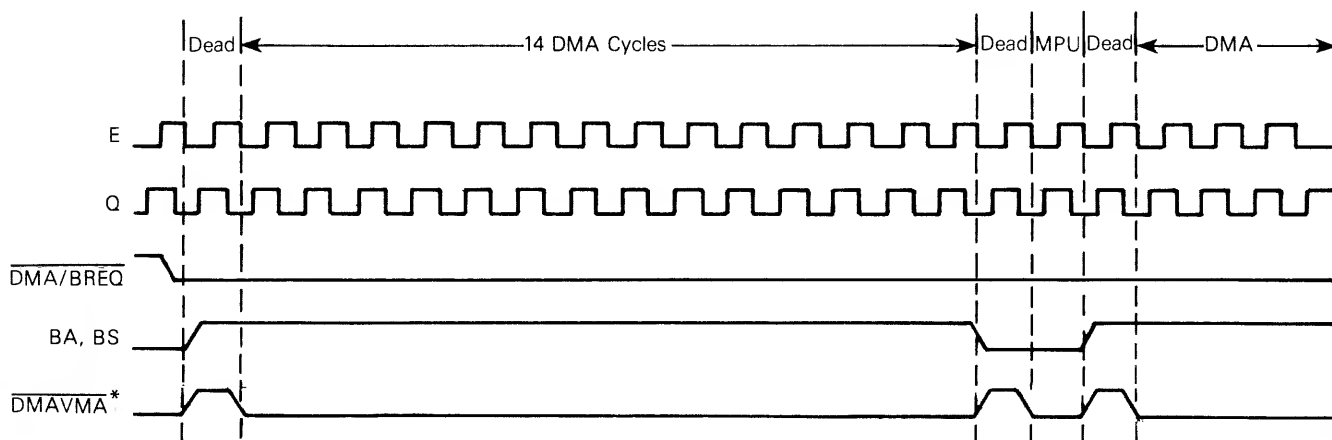

FIGURE 13 — TYPICAL DMA TIMING (< 14 CYCLES)

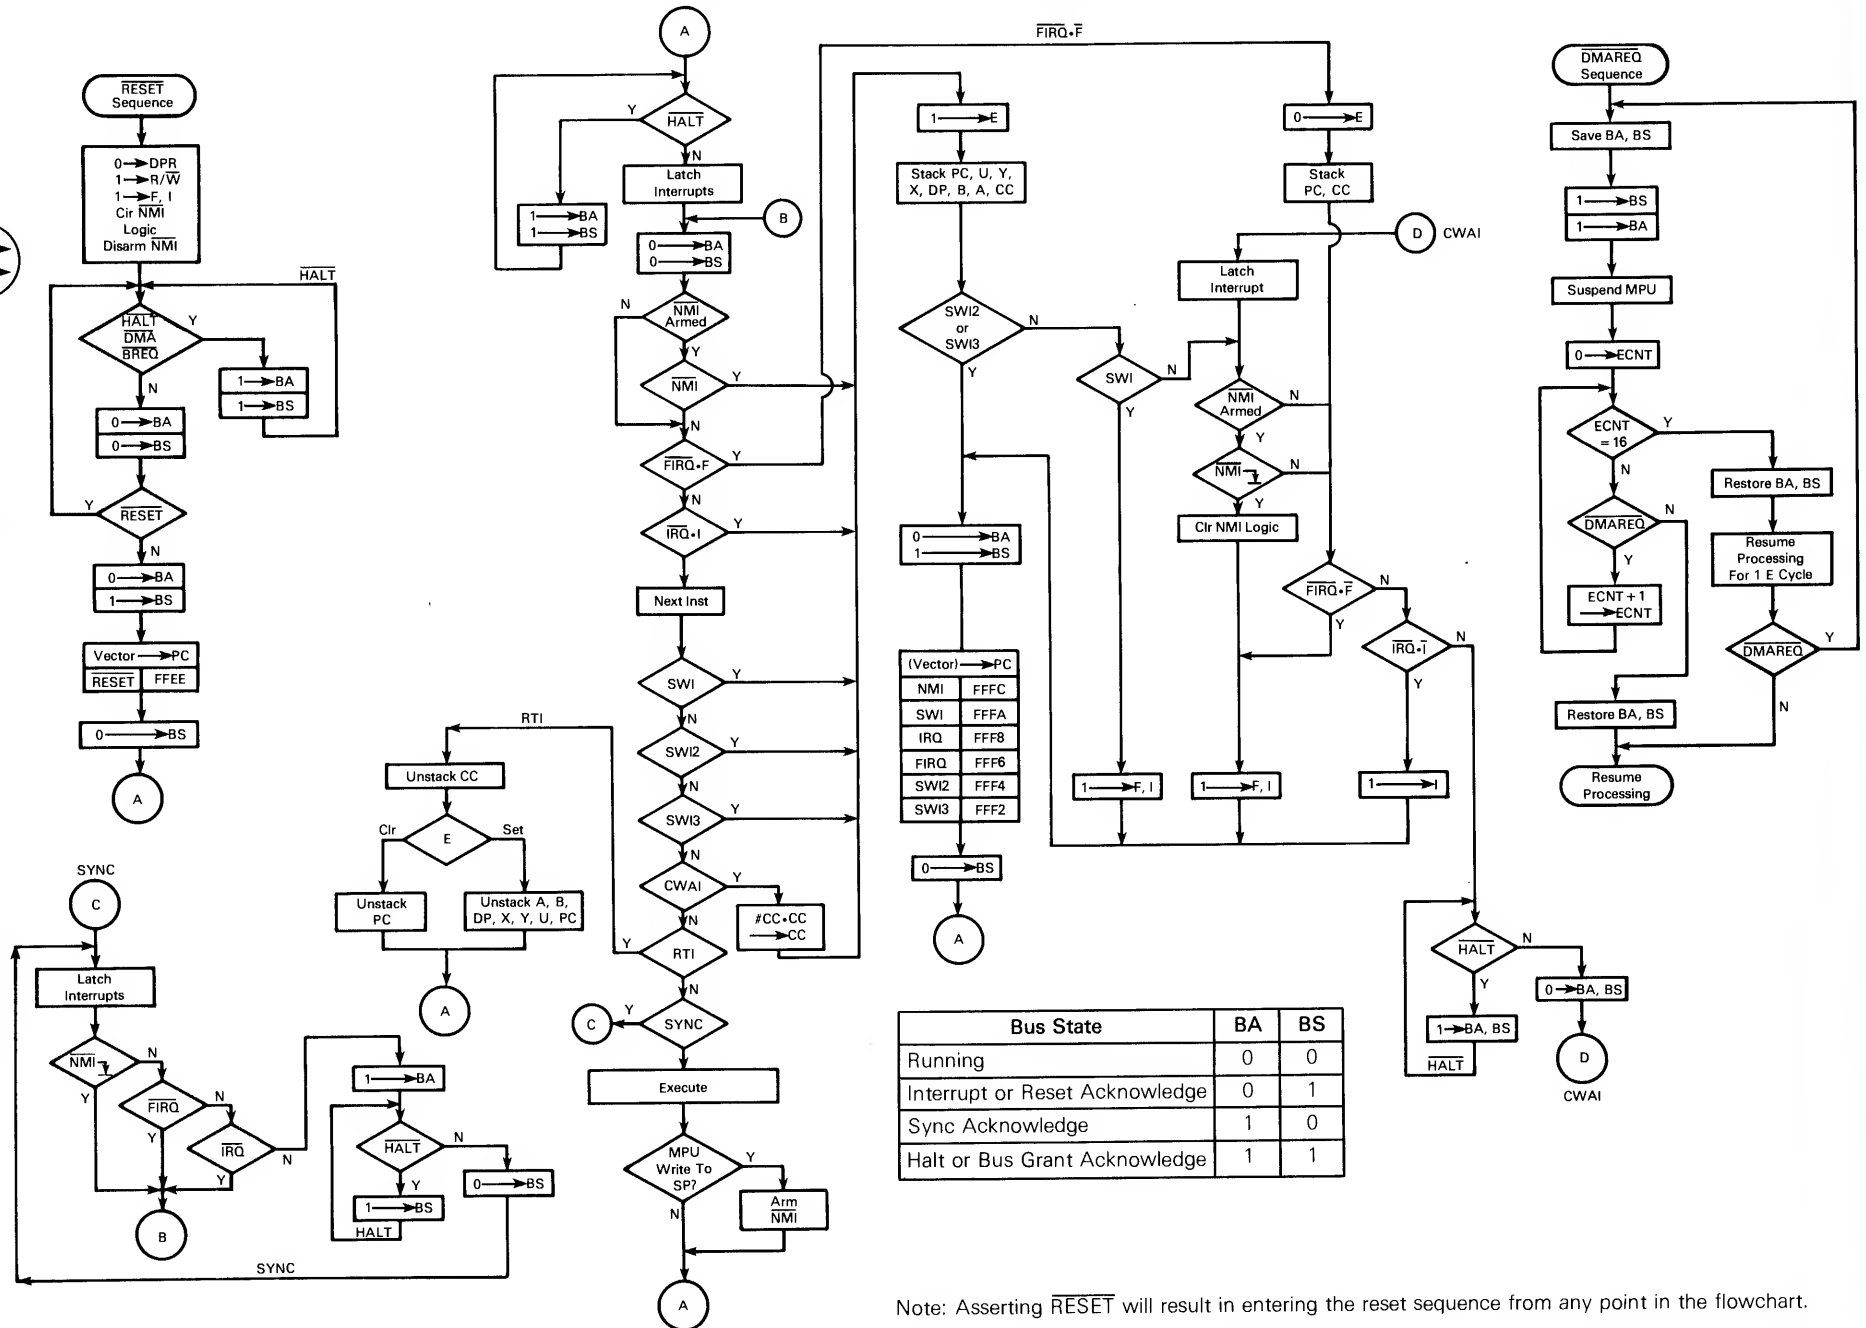

FIGURE 14 — AUTO-REFRESH DMA TIMING (> 14 CYCLES)
(REVERSE CYCLE STEALING)

* $\overline{\text{DMAVMA}}$ is a signal which is developed externally, but is a system requirement for DMA. Refer to Application Note AN-820.

NOTE: Waveform measurements for all inputs and outputs are specified at logic high 2.0 V and logic low 0.8 V unless otherwise specified.

FIGURE 15 — FLOWCHART FOR MC6809 INSTRUCTIONS

ADDRESSING MODES

The basic instructions of any computer are greatly enhanced by the presence of powerful addressing modes. The MC6809 has the most complete set of addressing modes available on any microcomputer today. For example, the MC6809 has 59 basic instructions; however, it recognizes 1464 different variations of instructions and addressing modes. The addressing modes support modern programming techniques. The following addressing modes are available on the MC6809:

- Inherent (includes accumulator)
- Immediate
- Extended
 - Extended Indirect
- Direct
- Register
- Indexed
 - Zero-Offset
 - Constant Offset
 - Accumulator Offset
 - Auto Increment/Decrement
 - Indexed Indirect
- Relative
 - Short/Long Relative Branching
 - Program Counter Relative Addressing

INHERENT (INCLUDES ACCUMULATOR)

In this addressing mode, the opcode of the instruction contains all the address information necessary. Examples of inherent addressing are: ABX, DAA, SWI, ASRA, and CLRB.

IMMEDIATE ADDRESSING

In immediate addressing, the effective address of the data is the location immediately following the opcode (i.e., the data to be used in the instruction immediately following the opcode of the instruction). The MC6809 uses both 8- and 16-bit immediate values depending on the size of argument specified by the opcode. Examples of instructions with immediate addressing are:

```
LDA #$20
LDX #$F000
LDY #CAT
```

NOTE

signifies Immediate addressing; \$ signifies hexadecimal value.

EXTENDED ADDRESSING

In extended addressing, the contents of the two bytes immediately following the opcode fully specify the 16-bit effective address used by the instruction. Note that the address generated by an extended instruction defines an absolute address and is not position independent. Examples of extended addressing include:

```
LDA CAT
STX MOUSE
LDD $2000
```

EXTENDED INDIRECT — As in the special case of indexed addressing (discussed below), one level of indirection may be added to extended addressing. In extended indirect, the two bytes following the postbyte of an indexed instruction contain the address of the data.

```
LDA [CAT]
LDX [$FFFE]
STU [DOG]
```

DIRECT ADDRESSING

Direct addressing is similar to extended addressing except that only one byte of address follows the opcode. This byte specifies the lower eight bits of the address to be used. The upper eight bits of the address are supplied by the direct page register. Since only one byte of address is required in direct addressing, this mode requires less memory and executes faster than extended addressing. Of course, only 256 locations (one page) can be accessed without redefining the contents of the DP register. Since the DP register is set to \$00 on reset, direct addressing on the MC6809 is compatible with direct addressing on the M6800. Indirection is not allowed in direct addressing. Some examples of direct addressing are:

```
LDA $30
SETDP $10 (assembler directive)
LDB $1030
LDD < CAT
```

NOTE

< is an assembler directive which forces direct addressing.

REGISTER ADDRESSING

Some opcodes are followed by a byte that defines a register or set of registers to be used by the instruction. This is called a postbyte. Some examples of register addressing are:

TFR	X, Y	Transfers X into Y
EXG	A, B	Exchanges A with B
PSHS	A, B, X, Y	Push Y, X, B and A onto S
PULU	X, Y, D	Pull D, X, and Y from U

INDEXED ADDRESSING

In all indexed addressing, one of the pointer registers (X, Y, U, S, and sometimes PC) is used in a calculation of the effective address of the operand to be used by the instruction. Five basic types of indexing are available and are discussed below. The postbyte of an indexed instruction specifies the basic type and variation of the addressing mode as well as the pointer register to be used. Figure 16 lists the legal formats for the postbyte. Table 2 gives the assembler form and the number of cycles and bytes added to the basic values for indexed addressing for each variation.

FIGURE 16 — INDEXED ADDRESSING POSTBYTE REGISTER BIT ASSIGNMENTS

Postbyte Register Bit								Indexed Addressing Mode
7	6	5	4	3	2	1	0	
0	R	R	d	d	d	d	d	EA = ,R + 5 Bit Offset
1	R	R	0	0	0	0	0	,R +
1	R	R	i	0	0	0	1	,R ++
1	R	R	0	0	0	1	0	, - R
1	R	R	i	0	0	1	1	, - - R
1	R	R	i	0	1	0	0	EA = ,R + 0 Offset
1	R	R	i	0	1	0	1	EA = ,R + ACCB Offset
1	R	R	i	0	1	1	0	EA = ,R + ACCA Offset
1	R	R	i	1	0	0	0	EA = ,R + 8 Bit Offset
1	R	R	i	1	0	0	1	EA = ,R + 16 Bit Offset
1	R	R	i	1	0	1	1	EA = ,R + D Offset
1	x	x	i	1	1	0	0	EA = ,PC + 8 Bit Offset
1	x	x	i	1	1	0	1	EA = ,PC + 16 Bit Offset
1	R	R	i	1	1	1	1	EA = [,Address]

Addressing Mode Field

Indirect Field
(Sign bit when b7 = 0)

Register Field: RR

x = Don't Care
d = Offset Bit
0 = Not Indirect
1 = Indirect

00 = X
01 = Y
10 = U
11 = S

ZERO-OFFSET INDEXED — In this mode, the selected pointer register contains the effective address of the data to be used by the instruction. This is the fastest indexing mode.

Examples are:

LDD O,X
LDA S

CONSTANT OFFSET INDEXED — In this mode, a two's-complement offset and the contents of one of the pointer registers are added to form the effective address of the operand. The pointer register's initial content is unchanged by the addition.

Three sizes of offsets are available:

5 bit (- 16 to + 15)
8 bit (- 128 to + 127)
16 bit (- 32768 to + 32767)

The two's complement 5-bit offset is included in the postbyte and, therefore, is most efficient in use of bytes and cycles. The two's complement 8-bit offset is contained in a single byte following the postbyte. The two's complement 16-bit offset is in the two bytes following the postbyte. In most cases the programmer need not be concerned with the size of this offset since the assembler will select the optimal size automatically.

Examples of constant-offset indexing are:

LDA 23,X
LDX -2,S
LDY 300,X
LDU CAT,Y

TABLE 2 — INDEXED ADDRESSING MODE

Type	Forms	Non Indirect		+ ~	+ #	Indirect		+ ~	+ #
		Assembler Form	Postbyte Opcode			Assembler Form	Postbyte Opcode		
Constant Offset From R	No Offset	,R	1RR00100	0	0	[,R]	1RR10100	3	0
(2s Complement Offsets)	5-Bit Offset	n, R	0RRnnnnn	1	0	defaults to 8-bit			
	8-Bit Offset	n, R	1RR01000	1	1	[n, R]	1RR11000	4	1
	16-Bit Offset	n, R	1RR01001	4	2	[n, R]	1RR11001	7	2
Accumulator Offset From R (2s Complement Offsets)	A Register Offset	A, R	1RR00110	1	0	[A, R]	1RR10110	4	0
	B Register Offset	B, R	1RR00101	1	0	[B, R]	1RR10101	4	0
	D Register Offset	D, R	1RR01011	4	0	[D, R]	1RR11011	7	0
Auto Increment/Decrement R	Increment By 1	,R +	1RR00000	2	0	not allowed			
	Increment By 2	,R ++	1RR00001	3	0	[,R ++]	1RR10001	6	0
	Decrement By 1	, - R	1RR00010	2	0	not allowed

	16-Bit Offset	n, PCR	1xx01101	5	2	[n, PCR]	1xx11101	8	2
Extended Indirect	16-Bit Address	-	-	-	-	[n]	10011111	5	2

R = X, Y, U, or S
x = Don't Care

RR:
00 = X
01 = Y
10 = U
11 = S

+ and # indicate the number of additional cycles and bytes for the particular variation.

ACCUMULATOR-OFFSET INDEXED — This mode is similar to constant offset indexed except that the two's-complement value in one of the accumulators (A, B, or D) and the contents of one of the pointer registers are added to form the effective address of the operand. The contents of both the accumulator and the pointer register are unchanged by the addition. The postbyte specifies which accumulator to use as an offset and no additional bytes are required. The advantage of an accumulator offset is that the value of the offset can be calculated by a program at run-time.

Some examples are:

```
LDA    B,Y
LDX    D,Y
LEAX   B,X
```

AUTO INCREMENT/DECREMENT INDEXED — In the auto increment addressing mode, the pointer register contains the address of the operand. Then, after the pointer register is used it is incremented by one or two. This addressing mode is useful in stepping through tables, moving data, or for the creation of software stacks. In auto decrement, the pointer register is decremented prior to use as the address of the data. The use of auto decrement is similar to that of auto increment; but the tables, etc., are scanned from the high to low addresses. The size of the increment/ decrement can be either one or two to allow for tables of either 8- or 16-bit data to be accessed and is selectable by the programmer. The pre-decrement, post-increment nature of these modes allows them to be used to create additional software stacks that behave identically to the U and S stacks.

Some examples of the auto increment/decrement addressing modes are:

```
LDA    ,X+
STD    ,Y++
LDB    , -Y
LDX    , - -S
```

Care should be taken in performing operations on 16-bit pointer registers (X, Y, U, S) where the same register is used to calculate the effective address.

Consider the following instruction:

```
STX 0,X++ (X initialized to 0)
```

The desired result is to store zero in locations \$0000 and \$0001 then increment X to point to \$0002. In reality, the following occurs:

```
0→temp    calculate the EA; temp is a holding register
X+2→X      perform auto increment
X→(temp)   do store operation
```

INDEXED INDIRECT — All of the indexing modes, with the exception of auto increment/decrement by one or a ± 4 -bit offset, may have an additional level of indirection specified. In indirect addressing, the effective address is contained at the location specified by the contents of the index register plus any offset. In the example below, the A accumulator is loaded indirectly using an effective address calculated from the index register and an offset.

Before Execution
A = XX (don't care)
X = \$F000

```
$0100    LDA    [$10,X]    EA is now $F010
```

```
$F010    $F1          $F150 is now the
$F011    $50          new EA
```

```
$F150    $AA
          After Execution
          A = $AA Actual Data Loaded
          X = $F000
```

All modes of indexed indirect are included except those which are meaningless (e.g., auto increment/decrement by one indirect). Some examples of indexed indirect are:

```
LDA    [,X]
LDD    [10,S]
LDA    [B,Y]
LDD    [,X++]
```

RELATIVE ADDRESSING

The byte(s) following the branch opcode is (are) treated as a signed offset which may be added to the program counter. If the branch condition is true, then the calculated address (PC + signed offset) is loaded into the program counter. Program execution continues at the new location as indicated by the PC; short (one byte offset) and long (two bytes offset) relative addressing modes are available. All of memory can be reached in long relative addressing as an effective address is interpreted modulo 2^{16} . Some examples of relative addressing are:

	BEQ	CAT	(short)
	BGT	DOG	(short)
CAT	LBEQ	RAT	(long)
DOG	LBGT	RABBIT	(long)
	•		
	•		
	•		
RAT	NOP		
RABBIT	NOP		

PROGRAM COUNTER RELATIVE — The PC can be used as the pointer register with 8- or 16-bit signed offsets. As in relative addressing, the offset is added to the current PC to create the effective address. The effective address is then used as the address of the operand or data. Program counter relative addressing is used for writing position independent programs. Tables related to a particular routine will maintain the same relationship after the routine is moved, if referenced relative to the program counter. Examples are:

```
LDA    CAT, PCR
LEAX   TABLE, PCR
```

Since program counter relative is a type of indexing, an additional level of indirection is available.

```
LDA    [CAT, PCR]
LDU    [DOG, PCR]
```

INSTRUCTION SET

The instruction set of the MC6809E is similar to that of the MC6800 and is upward compatible at the source code level. The number of opcodes has been reduced from 72 to 59, but because of the expanded architecture and additional addressing modes, the number of available opcodes (with different addressing modes) has risen from 197 to 1464.

Some of the new instructions are described in detail below.

PSHU/PSHS

The push instructions have the capability of pushing onto either the hardware stack (S) or user stack (U) any single register or set of registers with a single instruction.

PULU/PULS

The pull instructions have the same capability of the push instruction, in reverse order. The byte immediately following the push or pull opcode determines which register or registers are to be pushed or pulled. The actual push/pull sequence is fixed; each bit defines a unique register to push or pull, as shown below.

Push/Pull Postbyte

Stacking Order
Pull Order

CC
A
B
DPR
X Hi
X Lo
Y Hi
Y Lo
U/S Hi
U/S Lo
PC Hi
PC Lo

Push Order

Increasing
Memory

TFR/EXG

Within the MC6809E, any register may be transferred to or exchanged with another of like size, i.e., 8 bit to 8 bit or 16 bit to 16 bit. Bits 4-7 of postbyte define the source register, while bits 0-3 represent the destination register. These are denoted as follows:

Transfer/Exchange Postbyte

Source	Destination
--------	-------------

Register Field

0000 = D (A:B)	1000 = A
0001 = X	1001 = B
0010 = Y	1010 = CCR
0011 = U	1011 = DPR
0100 = S	
0101 = PC	

NOTE

All other combinations are undefined and INVALID.

LEAX/LEAY/LEAU/LEAS

The LEA (load effective address) works by calculating the effective address used in an indexed instruction and stores that address value, rather than the data at that address, in a pointer register. This makes all the features of the internal addressing hardware available to the programmer. Some of the implications of this instruction are illustrated in Table 3.

The LEA instruction also allows the user to access data and tables in a position independent manner. For example:

```
LEAX  MSG1, PCR
LBSR  PDATA (print message routine)
```

```
MSG1  FCC  'MESSAGE'
```

This sample program prints: 'MESSAGE'. By writing MSG1, PCR, the assembler computes the distance between the present address and MSG1. This result is placed as a constant into the LEAX instruction which will be indexed from the PC value at the time of execution. No matter where the code is located when it is executed, the computed offset from the PC will put the absolute address of MSG1 into the X pointer register. This code is totally position independent.

The LEA instructions are very powerful and use an internal holding register (temp). Care must be exercised when using the LEA instructions with the auto increment and auto decrement addressing modes due to the sequence of internal operations. The LEA internal sequence is outlined as follows:

LEAa ,b+ (any of the 16-bit pointer registers X, Y, U, or S may be substituted for a and b)

1. b → temp (calculate the EA)
2. b + 1 → b (modify b, postincrement)
3. temp → a (load a)

LEAa , - b

1. b - 1 → temp (calculate EA with predecrement)
2. b - 1 → b (modify b, predecrement)
3. temp → a (load a)

TABLE 3 — LEA EXAMPLES

Instruction	Operation	Comment
LEAX 10, X	$X + 10 \rightarrow X$	Adds 5-Bit Constant 10 to X
LEAX 500, X	$X + 500 \rightarrow X$	Adds 16-Bit Constant 500 to X
LEAY A, Y	$Y + A \rightarrow Y$	Adds 8-Bit A Accumulator to Y
LEAY D, Y	$Y + D \rightarrow Y$	Adds 16-Bit D Accumulator to Y
LEAU -10, U	$U - 10 \rightarrow U$	Subtracts 10 from U
LEAS -10, S	$S - 10 \rightarrow S$	Used to Reserve Area on Stack
LEAS 10, S	$S + 10 \rightarrow S$	Used to 'Clean Up' Stack
LEAX 5, S	$S + 5 \rightarrow X$	Transfers As Well As Adds

Auto increment-by-two and auto decrement-by-two instructions work similarly. Note that LEAX ,X+ does not change X; however, LEAX, -X does decrement; LEAX 1, X should be used to increment X by one.

MUL

Multiplies the unsigned binary numbers in the A and B accumulator and places the unsigned result into the 16-bit D accumulator. The unsigned multiply also allows multiple-precision multiplications.

LONG AND SHORT RELATIVE BRANCHES

The MC6809 has the capability of program counter relative branching throughout the entire memory map. In this mode, if the branch is to be taken, the 8- or 16-bit signed offset is added to the value of the program counter to be used as the effective address. This allows the program to branch anywhere in the 64K memory map. Position-independent code can be easily generated through the use of relative branching. Both short (8-bit) and long (16-bit) branches are available.

SYNC

After encountering a sync instruction, the MPU enters a sync state, stops processing instructions, and waits for an interrupt. If the pending interrupt is non-maskable (NMI) or maskable ($\overline{\text{FIRQ}}$, $\overline{\text{IRQ}}$) with its mask bit (F or I) clear, the processor will clear the sync state and perform the normal interrupt stacking and service routine. Since $\overline{\text{FIRQ}}$ and $\overline{\text{IRQ}}$ are not edge-triggered, a low level with a minimum duration of three bus cycles is required to assure that the interrupt will be taken. If the pending interrupt is maskable ($\overline{\text{FIRQ}}$, $\overline{\text{IRQ}}$) with its mask bit (F or I) set, the processor will clear the sync state and continue processing by executing the next in-line instruction. Figure 18 depicts sync timing.

SOFTWARE INTERRUPTS

A software interrupt is an instruction which will cause an interrupt and its associated vector fetch. These software interrupts are useful in operating system calls, software debugging, trace operations, memory mapping, and software development systems. Three levels of SWI are available on the MC6809, and are prioritized in the following order: SWI, SWI2, SWI3.

16-BIT OPERATION

The MC6809 has the capability of processing 16-bit data. These instructions include loads, stores, compares, adds, subtracts, transfers, exchanges, pushes, and pulls.

CYCLE-BY-CYCLE OPERATION

The address bus cycle-by-cycle performance chart (Figure 18) illustrates the memory-access sequence corresponding to each possible instruction and addressing mode in the MC6809. Each instruction begins with an opcode fetch. While that opcode is being internally decoded, the next program byte is always fetched. (Most instructions will use the next byte, so this technique considerably speeds throughput.) Next, the operation of each opcode will follow the flowchart. VMA is an indication of FFFF_{16} on the address bus, $\text{R}/\overline{\text{W}} = 1$ and $\text{BS} = 0$. The following examples illustrate the use of the chart.

Example 1: LBSR (Branch Taken)

Before Execution SP = F000

```

      •
      •
      •
$8000  LBSR  CAT
      •
      •
      •
$A000  CAT  •

```

CYCLE-BY-CYCLE FLOW

Cycle #	Address	Data	R/ $\overline{\text{W}}$	Description
1	8000	17	1	Opcode Fetch
2	8001	20	1	Offset High Byte
3	8002	00	1	Offset Low Byte
4	FFFF	*	1	VMA Cycle
5	FFFF	*	1	VMA Cycle
6	A000	*	1	Computed Branch Address
7	FFFF	*	1	VMA Cycle
8	FFFF	80	0	Stack High Order Byte of Return Address
9	FFFF	03	0	Stack Low Order Byte of Return Address

Example 2: DEC (Extended)

```

$8000  DEC  $A000
      •
      •
      •
$A8000 $80

```

CYCLE-BY-CYCLE FLOW

Cycle #	Address	Data	R/ $\overline{\text{W}}$	Description
1	8000	7A	1	Opcode Fetch
2	8001	A0	1	Operand Address, High Byte
3	8002	00	1	Operand Address, Low Byte
4	FFFF	*	1	VMA Cycle
5	A000	80	1	Read the Data
6	FFFF	*	1	VMA Cycle
7	A000	7F	0	Store the Decrement Data

* The data bus has the data at that particular address.

INSTRUCTION SET TABLES

The instructions of the MC6809 have been broken down into five different categories. They are as follows:

- 8-bit operation (Table 4)
- 16-bit operation (Table 5)
- Index register/stack pointer instructions (Table 6)
- Relative branches (long or short) (Table 7)
- Miscellaneous instructions (Table 8)

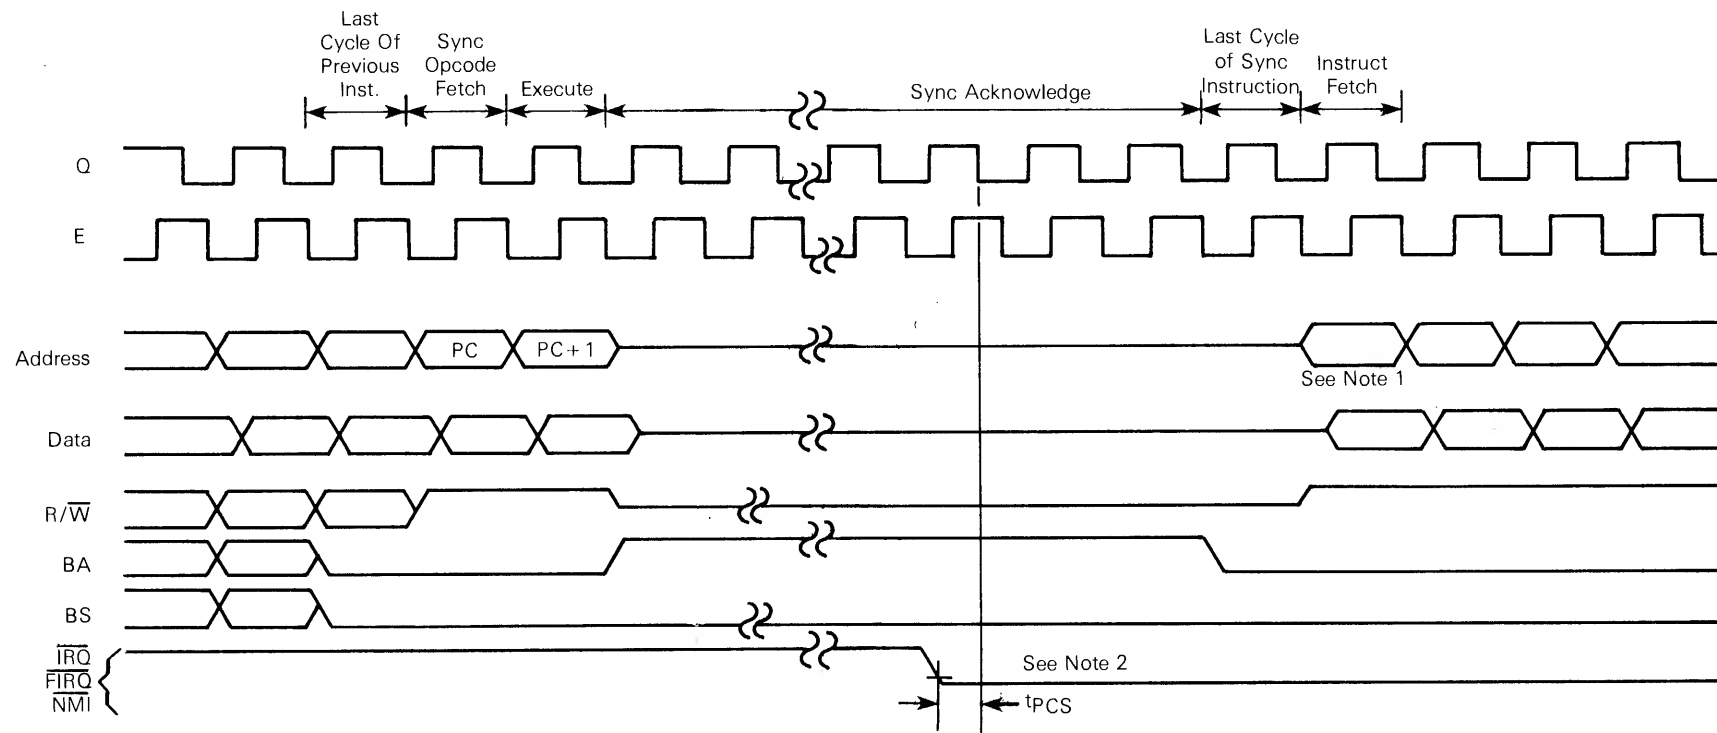

Hexadecimal values for the instructions are given in Table 9.

PROGRAMMING AID

Figure 19 contains a compilation of data that will assist in programming the MC6809.

FIGURE 17 — SYNC TIMING

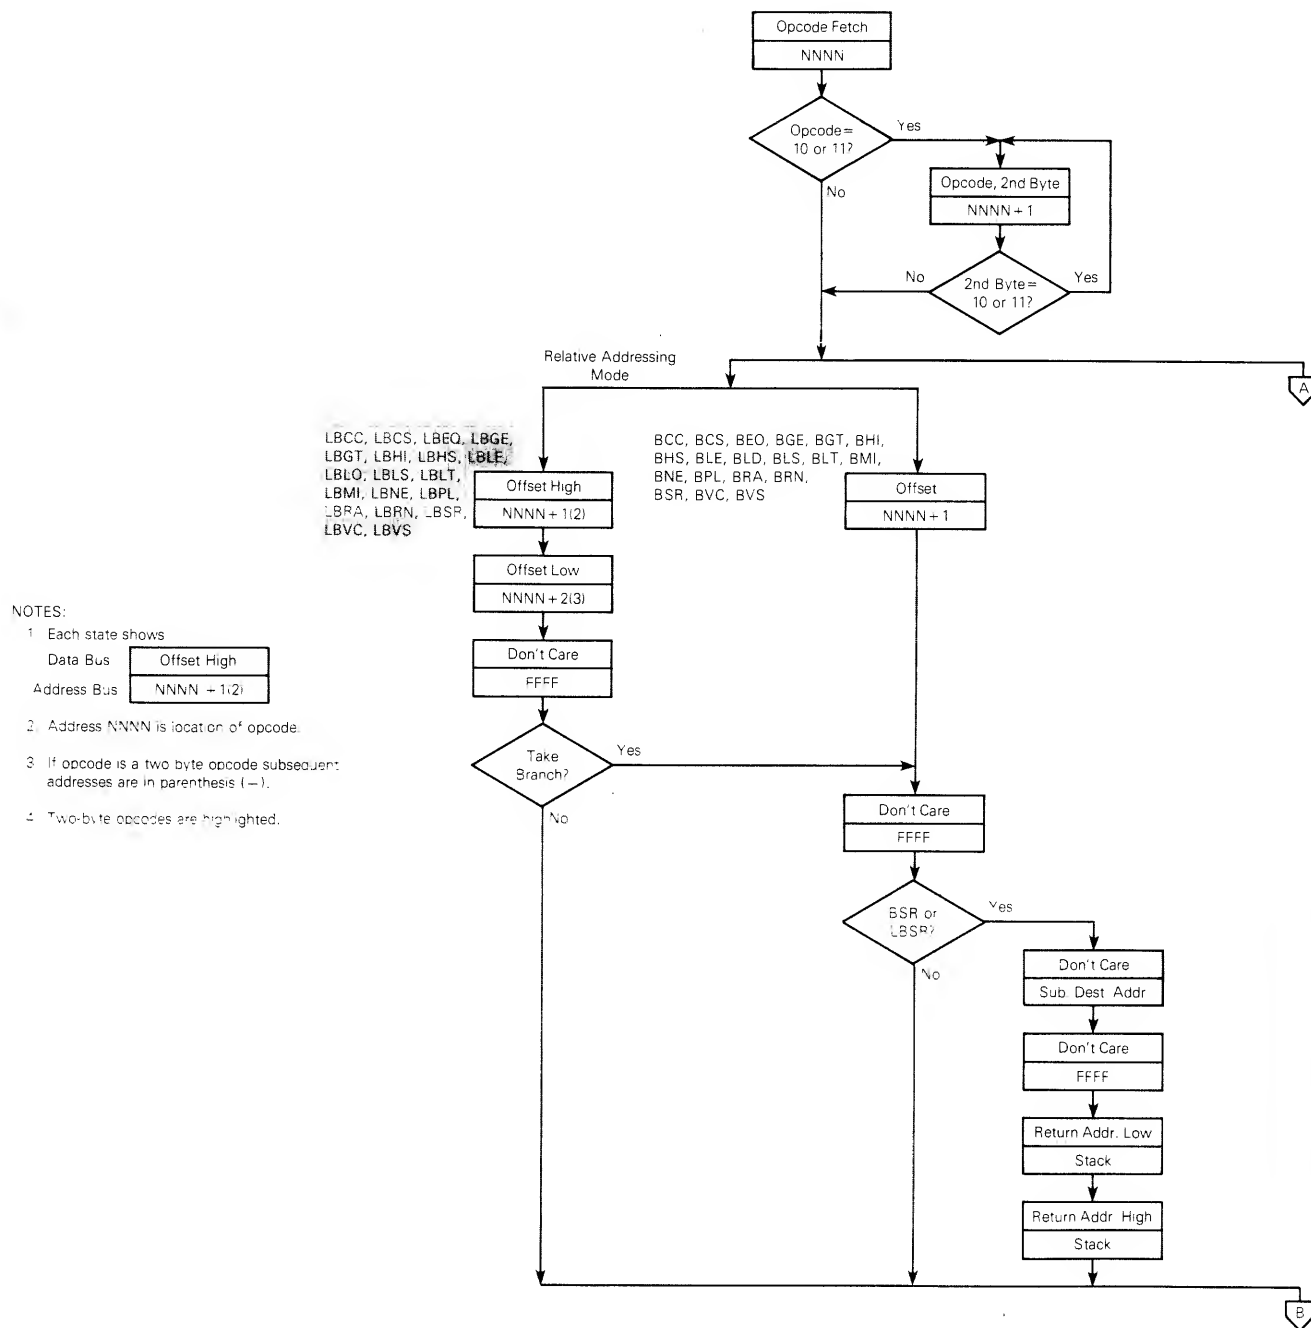

NOTES:

1. If the associated mask bit is set when the interrupt is requested, this cycle will be an instruction fetch from address location PC + 1. However, if the interrupt is accepted ($\overline{\text{NMI}}$ or an unmasked $\overline{\text{FIRQ}}$ or $\overline{\text{IRQ}}$) interrupt processing continues with this cycle as shown on Figures 9 and 10 (Interrupt Timing).
2. If mask bits are clear, $\overline{\text{IRQ}}$ and $\overline{\text{FIRQ}}$ must be held low for three cycles to guarantee interrupt to be taken, although only one cycle is necessary to bring the processor out of SYNC.
3. Waveform measurements for all inputs and outputs are specified at logic high 2.0 V and logic low 0.8 V unless otherwise specified.

FIGURE 18 — CYCLE-BY-CYCLE PERFORMANCE (Sheet 1 of 5)

NOTES:

- Each state shows
Data Bus: Offset High

TABLE 4 — 8-BIT ACCUMULATOR AND MEMORY INSTRUCTIONS

Mnemonic(s)	Operation
ADCA, ADCB	Add memory to accumulator with carry
ADDA, ADDB	Add memory to accumulator
ANDA, ANDB	And memory with accumulator
ASL, ASLA, ASLB	Arithmetic shift of accumulator or memory left
ASR, ASRA, ASRB	Arithmetic shift of accumulator or memory right
BITA, BITB	Bit test memory with accumulator
CLR, CLRA, CLRB	Clear accumulator or memory location
CMPA, CMPB	Compare memory from accumulator
COM, COMA, COMB	Complement accumulator or memory location
DAA	Decimal adjust A accumulator
DEC, DECA, DECB	Decrement accumulator or memory location
EORA, EORB	Exclusive or memory with accumulator
EXG R1, R2	Exchange R1 with R2 (R1, R2 = A, B, CC, DP)
INC, INCA, INCB	Increment accumulator or memory location
LDA, LDB	Load accumulator from memory
LSL, LSLA, LSLB	Logical shift left accumulator or memory location
LSR, LSRA, LSRB	Logical shift right accumulator or memory location
MUL	Unsigned multiply ($A \times B \rightarrow D$)
NEG, NEGA, NEGB	Negate accumulator or memory
ORA, ORB	Or memory with accumulator
ROL, ROLA, ROLB	Rotate accumulator or memory left
ROR, RORA, RORB	Rotate accumulator or memory right
SBCA, SBCB	Subtract memory from accumulator with borrow
STA, STB	Store accumulator to memory
SUBA, SUBB	Subtract memory from accumulator
TST, TSTA, TSTB	Test accumulator or memory location
TFR R1, R2	Transfer R1 to R2 (R1, R2 = A, B, CC, DP)

NOTE: A, B, CC, or DP may be pushed to (pulled from) stack with either PSHS, PSHU (PULS, PULU) instructions.

TABLE 5 — 16-BIT ACCUMULATOR AND MEMORY INSTRUCTIONS

Mnemonic(s)	Operation
ADDD	Add memory to D accumulator
CMPD	Compare memory from D accumulator
EXG D, R	Exchange D with X, Y, S, U, or PC
LDD	Load D accumulator from memory
SEX	Sign Extend B accumulator into A accumulator
STD	Store D accumulator to memory
SUBD	Subtract memory from D accumulator
TFR D, R	Transfer D to X, Y, S, U, or PC
TFR R, D	Transfer X, Y, S, U, or PC to D

NOTE: D may be pushed (pulled) to stack with either PSHS, PSHU (PULS, PULU) instructions.

TABLE 6 — INDEX REGISTER/STACK POINTER INSTRUCTIONS

Instruction	Description
CMPS, CMPU	Compare memory from stack pointer
CMPX, CMPY	Compare memory from index register
EXG R1, R2	Exchange D, X, Y, X, U, or PC with D, X, Y, S, U, or PC
LEAS, LEAU	Load effective address into stack pointer
LEAX, LEAY	Load effective address into index register
LDS, LDU	Load stack pointer from memory
LDX, LDY	Load index register from memory
PSHS	Push A, B, CC, DP, D, X, Y, U, or PC onto hardware stack
PSHU	Push A, B, CC, DP, D, X, Y, S, or PC onto user stack
PULS	Pull A, B, CC, DP, D, X, Y, U, or PC from hardware stack
PULU	Pull A, B, CC, DP, D, X, Y, S, or PC from hardware stack
STS, STU	Store stack pointer to memory
STX, STY	Store index register to memory
TFR R1, R2	Transfer D, X, Y, S, U or PC to D, X, Y, S, U, or PC
ABX	Add B accumulator to X (unsigned)

TABLE 7 — BRANCH INSTRUCTIONS

Instruction	Description
SIMPLE BRANCHES	
BEQ, LBEQ	Branch if equal
BNE, LBNE	Branch if not equal
BMI, LBMI	Branch if minus
BPL, LBPL	Branch if plus
BCS, LBCC	Branch if carry set
BCC, LBCC	Branch if carry clear
BVS, LBVS	Branch if overflow set
BVC, LBVC	Branch if overflow clear
SIGNED BRANCHES	
BGT, LBGT	Branch if greater (signed)
BVS, LBVS	Branch if invalid 2s complement result
BGE, LBGE	Branch if greater than or equal (signed)
BEQ, LBEQ	Branch if equal
BNE, LBNE	Branch if not equal
BLE, LBLE	Branch if less than or equal (signed)
BVC, LBVC	Branch if valid 2s complement result
BLT, LBLT	Branch if less than (signed)
UNSIGNED BRANCHES	
BHI, LBHI	Branch if higher (unsigned)
BCC, LBCC	Branch if higher or same (unsigned)
BHS, LBHS	Branch if higher or same (unsigned)
BEQ, LBEQ	Branch if equal
BNE, LBNE	Branch if not equal
BLS, LBLs	Branch if lower or same (unsigned)
BCS, LBCC	Branch if lower (unsigned)
BLO, LBLO	Branch if lower (unsigned)
OTHER BRANCHES	
BSR, LBSR	Branch to subroutine
BRA, LBRA	Branch always
BRN, LBRN	Branch never

TABLE 8 — MISCELLANEOUS INSTRUCTIONS

Instruction	Description
ANDCC	AND condition code register
CWAI	AND condition code register, then wait for interrupt
NOP	No operation
ORCC	OR condition code register
JMP	Jump
JSR	Jump to subroutine
RTI	Return from interrupt
RTS	Return from subroutine
SWI, SWI2, SWI3	Software interrupt (absolute indirect)
SYNC	Synchronize with interrupt line

NOTES:

1. This column gives a base cycle and byte count. To obtain total count, add the values obtained from the INDEXED ADDRESSING MODE table, Table 2.
2. R1 and R2 may be any pair of 8 bit or any pair of 16 bit registers.
The 8 bit registers are: A, B, CC, DP
The 16 bit registers are: X, Y, U, S, D, PC
3. EA is the effective address.
4. The PSH and PUL instructions require 5 cycles plus 1 cycle for each **byte** pushed or pulled.
5. 5(6) means: 5 cycles if branch not taken, 6 cycles if taken (Branch instructions).
6. SWI sets I and F bits. SWI2 and SWI3 do not affect I and F.
7. Conditions Codes set as a direct result of the instruction.
8. Value of half-carry flag is undefined.
9. Special Case — Carry set if b7 is SET.

SIMPLE BRANCHES

	OP	~	#
BRA	20	3	2
LBRA	16	5	3
BRN	21	3	2
LBRN	1021	5	4
BSR	8D	7	2
LBSR	17	9	3

SIMPLE CONDITIONAL BRANCHES (Notes 1-4)

Test	True	OP	False	OP
N = 1	BMI	2B	BPL	2A
Z = 1	BEQ	27	BNE	26
V = 1	BVS	29	BVC	28
C = 1	BCS	25	BCC	24

SIGNED CONDITIONAL BRANCHES (Notes 1-4)

Test	True	OP	False	OP
$r > m$	BGT	2E	BLE	2F
$r \geq m$	BGE	2C	BLT	2D
$r = m$	BEQ	27	BNE	26
$r \leq m$	BLE	2F	BGT	2E
$r < m$	BLT	2D	BGE	2C

UNSIGNED CONDITIONAL BRANCHES (Notes 1-4)

Test	True	OP	False	OP
$r > m$	BHI	22	BLS	23
$r \geq m$	BHS	24	BLO	25
$r = m$	BEQ	27	BNE	26
$r \leq m$	BLS	23	BHI	22
$r < m$	BLO	25	BHS	24

NOTES:

1. All conditional branches have both short and long variations.
2. All short branches are two bytes and require three cycles.
3. All conditional long branches are formed by prefixing the short branch opcode with \$10 and using a 16-bit destination offset.
4. All conditional long branches require four bytes and six cycles if the branch is taken or five cycles if the branch is not taken.

PACKAGE DIMENSIONS

DIM	MILLIMETERS		INCHES	
	MIN	MAX	MIN	MAX
A	51.69	52.45	2.035	2.065
B	13.72	14.22	0.540	0.560
C	3.94	5.08	0.155	0.200
D	0.36	0.56	0.014	0.022
F	1.02	1.52	0.040	0.060
G	2.54 BSC		0.100 BSC	
H	1.65	2.16	0.065	0.085
J	0.20	0.38	0.008	0.015
K	2.92	3.43	0.115	0.135
L	15.24 BSC		0.600 BSC	
M	0°	15°	0°	15°
N	0.51	1.02	0.020	0.040

NOTES:

1. POSITIONAL TOLERANCE OF LEADS (D), SHALL BE WITHIN 0.25 mm (0.010) AT MAXIMUM MATERIAL CONDITION, IN RELATION TO SEATING PLANE AND EACH OTHER.
2. DIMENSION L TO CENTER OF LEADS WHEN FORMED PARALLEL.
3. DIMENSION B DOES NOT INCLUDE MOLO FLASH.

M	—	10°	—	10°
N	1.02	1.52	0.040	0.060

NOTES:

1. DIMENSION A IS DATUM.
2. POSITIONAL TOLERANCE FOR LEADS:

$$\pm 0.25 (0.010) \text{ (M) } T \text{ (A) } \text{ (M)}$$

3. T IS SEATING PLANE.
4. DIMENSION "L" TO CENTER OF LEADS WHEN FORMED PARALLEL.
5. DIMENSIONING AND TOLERANCING PER ANSI Y14.5, 1973.
